

Offline-first, or it *doesn't ship*.

The one design rule I never break.

22% have steady *internet.*

In the markets I build for, connectivity is the exception, not the rule. An app that needs the cloud to work is an app that does not work.

Build for the *worst signal.*

- **Local-first data** the app works fully with no connection
- **Sync when you can** queues that catch up the moment signal returns
- **Graceful degradation** never a blank screen, always a next action
- **Conflict handling** two offline edits should not lose data

It's not a feature.
It's *respect*.

A clinic does not stop because the tower is down. Neither should the software a clinician relies on.

Hard constraints make *honest tools*.

Welbodi and LMIS are both offline-first. The constraint made them better, not weaker.

YOUR MOVE

Shipping to low *connectivity*?

Save this and follow for more field-tested principles.

DM me "MVP" to build offline-first from day one.
